Abstract
We introduce a family of signatures for finite metric spaces, possibly endowed with real valued functions, based on the persistence diagrams of suitable filtrations built on top of these spaces. We prove the stability of our signatures under Gromov-Hausdorff perturbations of the spaces. We also extend these results to metric spaces equipped with measures. Our signatures are well-suited for the study of unstructured point cloud data, which we illustrate through an application in shape classification.

Categories and Subject Descriptors (according to ACM CCS): I.3.5 [Computer Graphics]: Computational Geometry and Object Modelling—

1. Introduction
In recent years, great advances have been made in the fields of data acquisition and shape modelling, and huge collections of digital models have been obtained. With the goal of organizing these collections, it is very important to be able to define and compute meaningful notions of similarity between objects that exhibit invariance to different deformations or poses of the objects represented by the data. Problems of this nature arise in areas such as molecular biology, metagenomics, face recognition, matching of articulated objects, graph matching, and pattern recognition in general.

In many practical applications, data are endowed with a notion of distance between their points, which turns them into metric spaces. The information contained in such data sets typically takes the form of metric invariants, which is of interest to capture and characterize. For instance, when the data have been obtained experimentally, the analysis of these invariants can provide insights about the nature of the underlying phenomenological science.

Relevant work. In the context of shape analysis, one typically wishes to be able to discriminate shapes under different notions of invariance. Many approaches have been proposed for the problem of (pose invariant) shape classification and recognition, including the size theory of Frosini and collaborators [Fro90, CFL06a, CFL06b], the work of Hilaga et al. [HSKK01], the shape contexts [BMP02], the integral invariants of [MCH\textsuperscript{*}06], the eccentricity functions of [HK03], the shape distributions of [OFCD02], the canonical forms of [EK03], and the shape DNA and global point signatures based spectral methods in [RWP05] and [Rus07], respectively. The common underlying idea revolves around the computation and comparison of certain metric invariants, or signatures, so as to ascertain whether two given data sets represent in fact the same object, up to a certain notion of invariance.

The question of proving that a given family of signatures is indeed able to signal proximity or similarity of shapes in a reasonable way has been hardly addressed. In particular, the degree to which two shapes with similar signatures are forced to be similar is in general not well understood. Conversely, one can ask the more basic question of whether the similarity between two shapes forces their signatures to be similar. These questions cannot be completely well formulated until one agrees on: (1) a notion of equality between shapes, and (2) a notion of (dis)similarity between shapes.

By regarding sampled shapes as finite metric spaces, one can use the Gromov-Hausdorff distance [Gro99] as a measure of dissimilarity between shapes [MS04, MS05]. By endowing the point clouds with different metrics, one obtains a great deal of flexibility in the different degrees of invariance that one can encode in the measure of dissimilarity. For instance, using the Euclidean metric in $\mathbb{R}^d$ makes the Gromov-Hausdorff distance invariant under ambient rigid isom-
tries [Mém08]. In contrast, using intrinsic metrics within the shapes makes the Gromov-Hausdorff distance blind to intrinsic isometries, such as when a same animal is represented in different poses (Figure 1). Bronstein et al. [BBK09] suggested to combine intrinsic and extrinsic metrics to increase the discriminating power of shape signatures. We illustrate this idea in Figure 6, where the first two shapes (circle and helicoidal curve on a torus) have same length and are therefore isometric embeddings of a same object into $\mathbb{R}^3$. As a result, signatures obtained from geodesic distances are identical whereas signatures based on Euclidean distances differ.

**Figure 1: The database of shapes used in our experiments.**

Once the finite metric space representation of shapes has been adopted, the question becomes whether a given family of signatures is stable under perturbations of the shape in the Gromov-Hausdorff distance. A somewhat different version of the problem is when the spaces are endowed with measures, a case in which perturbations are understood in the sense of the $(l^\infty)$ Gromov-Wasserstein distance [Mém07]. These questions about stability of invariants are addressed in [Mém07] for a limited set of signatures [HK03, MCH*06, BMP02, OFCD02].

**Our contributions.** Using tools from persistent homology [ELZ00, ZC05], we construct a novel class of Gromov-Hausdorff stable metric invariants. Our approach is in the spirit of [CZCG05] and [dFL06, dFL05] in that we try to devise certain topologically motivated signatures that naturally combine the classificatory power of topology with the flexibility of metrics.

We enrich the pool of shape signatures available in the literature in two ways (see Section 3):

- First, we extend zero-dimensional connectivity-based signatures such as the dendrograms of [CM09] or the invariants computed by size theory [dFL06, dFL05] to higher-dimensional homology classes, and we prove their stability under small Gromov-Hausdorff perturbations. This greatly increases the discriminative power of the approach, as illustrated in Figure 6, where all shapes have been $\varepsilon$-sampled for a same value of $\varepsilon$ and therefore all zero-dimensional diagrams are the same (rows 2 and 3).

- Second, we extend the approach to the case of metric spaces endowed with real-valued functions. This latter step enables the design of new signatures for finite metric spaces by considering canonically-defined functions on these spaces, such as eccentricities (Section 4). As a result, more shapes can be discriminated using our approach. For instance, in Figure 6, the sphere and ellipsoid cannot be discriminated using standard Rips filtrations (see Definition 2.7) because their diagrams are the same up to rescaling and small noise (rows 2 and 3). In contrast, using a fraction of the eccentricity as function modifies the shapes of the 1- and 2-dimensional diagrams of the ellipsoid significantly, while the ones for the sphere hardly change due to the fact that the eccentricity is constant (row 4).

Our signatures are also adapted to deal with measure metric spaces [Gro99, Chapter 3], where additional information is provided in the form of a collection of weights, one per point of the shape. In this case, stability is guaranteed under small perturbations in the Gromov-Wasserstein distance (Section 5).

Since the computation of the Gromov-Hausdorff distance leads to hard combinatorial problems akin to the quadratic assignment problem (which is NP hard), the construction of easily computable Gromov-Hausdorff stable invariants is very important. We show in Section 6 that the computation of our invariants yields simple bottleneck assignment problems, which can be solved in polynomial time. In contrast with other approaches that generally involve some delicate numerical algorithms and/or require the availability of a mesh of the underlying object [MS04, BBK06], the algorithm for computing and comparing our signatures is entirely combinatorial and can be applied on the sole input of a distance matrix.

Finally, our invariants prove to be useful for discriminating between different classes of shapes in a classification task performed on the database of Figure 1. The results are presented in Section 7.

2. Mathematical background

2.1. Metric spaces and Gromov-Hausdorff distance(s)

Recall that a metric space is a pair $(X, d_X)$ where $X$ is a set and $d_X : X \times X \to \mathbb{R}$ is a non-negative function such that for any $x, y, z \in X$, $d_X(x, y) = 0$ if and only if $x = y$, $d_X(x, y) = d_X(y, x)$ and $d_X(x, z) \leq d_X(x, y) + d_X(y, z)$.

In the sequel $X$ denotes the collection of all compact metric spaces. Two compact spaces $(X, d_X)$ and $(Y, d_Y)$ are said to be *isometric* if there exists a bijection $\phi : X \to Y$ that preserves distances, namely: $\forall x, x' \in X$, $d_Y(\phi(x), \phi(x')) = d_X(x, x')$. Such a map is called an *isometry*. The set of isometry classes of compact metric spaces can be endowed with a distance called the Gromov-Hausdorff distance [BBI01, Thm. 7.3.30], whose definition uses the following notion of correspondence between sets [BBI01, Def. 7.3.17]:

© 2009 The Author(s)
Definition 2.1 A correspondence between two sets $X$ and $Y$ is a subset $C \subseteq X \times Y$ such that: $\forall x \in X, \exists y \in Y$ s.t. $(x, y) \in C$, and $\forall y \in Y, \exists x \in X$ s.t. $(x, y) \in C$. The set of all correspondences between $X$ and $Y$ is denoted $\mathcal{C}(X, Y)$.

Definition 2.2 The Gromov-Hausdorff distance between compact metric spaces $(X, d_X), (Y, d_Y)$ is:
\[
d_{GH}((X, d_X), (Y, d_Y)) = \frac{1}{2} \inf_{C \in \mathcal{C}(X, Y)} \|\Gamma_{X,Y}\|_{\infty} (C \times C),
\]
where $\Gamma_{X,Y} : X \times Y \times X \times Y \to \mathbb{R}^+$ is defined by $(x, y, x', y') \mapsto |d_X(x, x') - d_Y(y, y')|$ and the notation $\|\Gamma_{X,Y}\|_{\infty} (C \times C)$ stands for $\sup_{(x,y),(x',y') \in C} \Gamma_{X,Y}(x,y,x',y')$.

Another way of defining the Gromov-Hausdorff distance is via common isometric embeddings of the two spaces. Specifically, given two compact subsets $X, Y$ of a same metric space $(Z, d_Z)$, the Hausdorff distance between $X$ and $Y$ is the quantity:
\[
d_H^Z(X, Y) = \max \{ \max_{x \in X} \min_{y \in Y} d_Z(x, y), \min_{y \in Y} \max_{x \in X} d_Z(x, y) \}.
\]

The Gromov-Hausdorff distance is then defined as follows:

Definition 2.3 The Gromov-Hausdorff distance between compact metric spaces $(X, d_X), (Y, d_Y)$ is:
\[
d_{GH}(X, Y) = \inf_{Z, \phi, \gamma} \max_{x \in X} \min_{y \in Y} d_Z(\phi(x), \gamma(y)),
\]
where $\gamma, \gamma'$ range over all the isometric embeddings of $X, Y$ into some same metric space $(Z, d_Z)$.

Definitions 2.2 and 2.3 are known to be equivalent [BBIO1, Thm. 7.3.25]. In particular, when the spaces are compact, the proof of equivalence shows that the infima in Eqs. (1) and (2) are in fact minima.

We now turn our focus to compact metric spaces endowed with continuous real-valued functions. Let $X_1$ be the collection of all such spaces:
\[X_1 = \{ (X, d_X, f_X) | (X, d_X) \in X, f_X : X \to \mathbb{R} \text{ continuous} \}.
\]

We deem two spaces $X, Y \in X_1$ isomorphic whenever there exists an isometry $\phi : X \to Y$ s.t. $f_Y = f_X \circ \phi$. We then extend the Gromov-Hausdorff distance as follows:

Definition 2.4 Given $X, Y \in X_1$, $d_{GH}(X, Y) = \inf_{C \in \mathcal{C}(X, Y)} \max \left\{ \frac{1}{2} \|\Gamma_{X,Y}\|_{\infty} (C \times C), \|f_X - f_Y\|_{\infty} (C) \right\}$

where $\|f_X - f_Y\|_{\infty} (C)$ stands for $\sup_{(x,y) \in C} |f_X(x) - f_Y(y)|$.

Note that if $f_X$ and $f_Y$ are equal constant functions, then one recovers $d_{GH}$.

As in the case of the standard Gromov-Hausdorff distance, the infimum in Eq. (3) is a minimum when the spaces are compact. Moreover, the proof of [BBIO1, Thm. 7.3.25] shows that, for any correspondence $C \in \mathcal{C}(X, Y)$, the disjoint union $X \cup Y$ can be endowed with a metric $d_C$ that coincides with $d_X$ over $X \times X$ and with $d_Y$ over $Y \times Y$, and such that we have $d_C(x, y) \leq \frac{1}{2} \|\Gamma_{X,Y}\|_{\infty} (C \times C)$ and $|f_X(x) - f_Y(y)| \leq \|f_X - f_Y\|_{\infty} (C)$ whenever $(x, y) \in C$.

Theorem 2.5 $d_{GH}$ defines a metric on the set of isomorphism classes of $X_1$.

The proof of this result is a direct adaptation of the proof [BBIO1, Thm. 7.3.30].

2.2. Filtrations, persistence diagrams and stability

Throughout the paper we consider simplicial homology with coefficients in a field, and we make a large use of topological persistence theory [ELZ00, ZC05]. Thorough introductions to these subjects can be found in [Mun84, EH, CCS07]. Recall that a simplicial complex $K$ is a finite collection of simplices such that every face of a simplex of $K$ is also in $K$ and the intersection of any two simplices is either empty or a common face of each of them. A filtration $\mathcal{K}$ of a simplicial complex $K$ is a nested sequence of subcomplexes $\emptyset = K_0 \subseteq K_1 \subseteq \cdots \subseteq K_n = K$, where $K_0 < K_1 < \cdots < K_n$ is an ordered sequence of real numbers. The inclusion maps between the subcomplexes induce a directed system of vector spaces, called a persistence module, involving their $k$-dimensional homology groups:
\[
H_k(K_0) \to H_k(K_1) \to \cdots \to H_k(K_n).
\]

The structure of this persistence module can be encoded as a multi-set of points $D_k\mathcal{K}$, called the $k$-th persistence diagram of $\mathcal{K}$ (see Figure 2). Intuitively, each point $p \in D_k\mathcal{K}$ encodes the lifespan of some $k$-dimensional homological feature appearing at time $p_k$ and dying at time $p_t$ in the filtration $\mathcal{K}$. More formally, $D_k\mathcal{K}$ is a multi-subset of the extended plane $\mathbb{R} \cup \{ -\infty, +\infty \}$, contained in the union of the extended diagonal $\Delta = \{ (x, x) : x \in \mathbb{R} \}$ and of the grid $\{ (a_0, \cdots, a_n) \times (\alpha_0, \cdots, \alpha_n, \alpha_\infty = +\infty \}$. The multiplicity of the points of $\Delta$ is set to $+\infty$, while the multiplicities of the $(\alpha_0, \alpha_j), 0 \leq i < j \leq +\infty$, are defined in terms of the ranks of the homomorphisms $\phi^n_j = \phi^{n-1}_j \circ \cdots \circ \phi^0_j$. See [CCSG09] for a precise definition.

The concept of persistence extends to the case of a filtration defined by the sublevel-sets of a continuous function $f : X \to \mathbb{R}$, under some tameness condition [CSEH05] stating that the family of inclusions $f^{-1}((-\infty, \alpha]) \subseteq f^{-1}((-\infty, \beta])$ induces at $k$-dimensional homology level a persistence module of the same (finite) type as in Eq. (4). The definition of $k$-th persistence diagram of such a function carries over. The use of persistence to devise signatures is motivated by the following stability property:

Theorem 2.6 (Stability [CSEH05]) Let $X$ be a triangulable space and $f, g : X \to \mathbb{R}$ two tame continuous functions. Then, the bottleneck distance between the persistence diagrams of $f$ and $g$ in the extended plane $\mathbb{R}_\infty$ is at most $\|f - g\|_{\infty}$.

Recall that the bottleneck distance $d_{BC}(A, B)$ between two
multi-sets in \((\mathbb{R}^2, l^\infty)\) is the quantity \(\min_\gamma \max_{p \in A} \|p - \gamma(p)\|_{\infty}\), where \(\gamma\) ranges over all bijections from \(A\) to \(B\).

Theorem 2.6 has been recently extended to wider classes of functions and spaces using a new notion of proximity between persistence modules called \(\varepsilon\)-interleaving [CCSG’09]. This extended stability result will be instrumental in the proof of Theorem 3.2.

From a practical point of view, the persistence diagrams of a given filtration can be efficiently computed using the so-called Rips filtration \(\mathcal{R}(X, d_X)\) containing 4,950 edges and 161,700 triangles. The simplices are colored according to their time of appearance in the filtration, from light blue to orange. Bottom row: the 0-dimensional (left) and 1-dimensional (right) persistence diagrams of \(\mathcal{R}(X, d_X)\).

**Definition 2.7** Given a finite metric space \((X, d_X)\) and a parameter \(\alpha > 0\), the Rips complex \(R\alpha(X, d_X)\) is the abstract simplicial complex of vertex set \(X\), whose simplices correspond to the non-empty subsets of \(X\) of diameter less than \(2\alpha\) in the metric \(d_X\). The Rips filtration of \((X, d_X)\), noted \(\mathcal{R}(X, d_X)\), is the nested family of Rips complexes obtained by varying parameter \(\alpha\) from 0 to \(+\infty\). When \(X\) is endowed with a real valued function \(f\), we define a filtration \(\mathcal{R}(X, d_X, f) = \{R\alpha(X, d_X)\}_{\alpha > 0}\) where \(X_\alpha\) denotes the set \(f^{-1}((\infty, \alpha]) \subseteq X\).

It has been shown in [CO08] that for well-chosen values of \(\alpha\), the Rips complex \(R\alpha(X, d_X)\) of a finite metric space \((X, d_X)\) can be used to recover the homology of an unknown shape that is sufficiently densely sampled by \(X\). In this paper, we adopt a more general point of view by studying the stability properties of the entire Rips filtration \(\mathcal{R}(X, d_X)\).

### 2.3. Technical results

The following results will be used in the proofs but are not necessary to understand the general approach. We begin with a standard result (see e.g. example 3.5.3 and exercise 3.5.4 of [BB01]) that will be key in the next section:

**Lemma 2.8** Any finite metric space of cardinality \(n\) can be isometrically embedded into \((\mathbb{R}^1, l^\infty)\).

In view of this lemma, Rips filtrations of finite subsets \(X\) of \(\mathbb{R}^n\) endowed with the \(l^\infty\)-distance are of particular interest for the rest of the paper. In particular they are closely related to the so-called \(\check{C}ech\) filtration of \(X\) within \((\mathbb{R}^n, l^\infty)\), which is also defined as a nested family of abstract simplicial complexes of vertex set \(X\). Specifically, for all \(\alpha > 0\), the simplices of \(C\alpha(X, \mathbb{R}^n, l^\infty)\) correspond to the non-empty subsets of \(X\) that are centers of open \(l^\infty\)-balls of same radius \(\alpha\) with a non-empty common intersection in \(\mathbb{R}^n\).

**Lemma 2.9** ([GM05]) For any finite set \(X \subseteq \mathbb{R}^n\) and any \(\alpha > 0\), one has \(C\alpha(X, \mathbb{R}^n, l^\infty) = R\alpha(X, l^\infty)\).

Note that the \(\check{C}ech\) complex \(C\alpha(X, \mathbb{R}^n, l^\infty)\) is nothing but the nerve of the collection of open \(l^\infty\)-balls of same radius \(\alpha\) about the points of \(X\). The topological structures of unions of open balls in \((\mathbb{R}^n, l^\infty)\) are related to the ones of their nerves through the following extension of the Nerve Lemma which, more generally, relates good open covers to their nerves. Given a topological space \(S\) and a family \(\mathcal{U} = \{U_x\}_{x \in X}\) of open subsets covering \(S\), the family defines a good cover if for every finite subset \(Y\) of \(X\) the common intersection \(\bigcap_{x \in Y} U_x\) is either empty or contractible. The nerve \(\mathcal{N}\mathcal{U}\) is the abstract simplicial complex of vertex set \(X\) such that \(x_0, \ldots, x_k\) form a simplex if and only if \(U_{x_0} \cap \cdots \cap U_{x_k} \neq \emptyset\).

**Lemma 2.10** (Persistent Nerve [CO08]) Let \(S \subseteq S'\) be two paracompact spaces, and let \(\mathcal{U} = \{U_x\}_{x \in X}\) and \(\mathcal{U}' = \{U_x'\}_{x' \in X'}\) be good open covers of \(S\) and \(S'\) respectively, based on finite parameter sets \(X \subseteq X'\) such that \(U_x \subseteq U_x'\) for all \(x \in X\). Then, the homotopy equivalences \(\mathcal{N}\mathcal{U} \rightarrow S\) and \(\mathcal{N}\mathcal{U}' \rightarrow S'\) provided by the Nerve Theorem [Hat01, §4G] commute with the canonical inclusions \(S \hookrightarrow S'\) and \(\mathcal{N}\mathcal{U} \hookrightarrow \mathcal{N}\mathcal{U}'\) at homology level.
3. Persistence based lower bounds for Gromov-Hausdorff distance

Computing the Gromov-Hausdorff distance between two finite metric spaces appears to be practically intractable in most cases. To distinguish such spaces from a metric point of view, it is thus important to exhibit reasonable lower bounds whose computation is tractable. The results of this section show that the bottleneck distances between persistence diagrams of Rips filtrations of finite metric spaces are reasonable lower bounds.

**Theorem 3.1** For any finite metric spaces $(X,d_X)$ and $(Y,d_Y)$, for any $k \in \mathbb{N}$,
\[
d^\text{GH}_k(D_kR(X,d_X), R(Y,d_Y)) \leq d_{\text{GH}}((X,d_X), (Y,d_Y)).
\]

Note that this lower bound on the Gromov-Hausdorff distance is tight. For instance, take for $X$ two sets of two points at distance 2 and for $Y$ a set of two points at distance $2 + \epsilon$. Then, $(X,d_X)$ and $(Y,d_Y)$ can be isometrically embedded into the real line, with $X$ mapped to $[0,2]$ and $Y$ mapped to $[-\epsilon, 2 + \epsilon]$, which shows that their Gromov-Hausdorff distance is at most $\epsilon$. Now, the 0-dimensional persistence diagram of the Rips filtration of $(X,d_X)$ is made of two points, namely $(0,+\infty)$ and $(0,1)$, while the 0-dimensional persistence diagram of the Rips filtration of $(Y,d_Y)$ is made of $(0,+\infty)$ and $(0,1 + \epsilon)$, hence their bottleneck distance is $\epsilon$.

**Proof of Theorem 3.1.** Let $\epsilon = d_{\text{GH}}((X,d_X), (Y,d_Y))$. As mentioned after Definition 2.3, the infimum in Eq. (2) is in fact a minimum, which means that there is a metric space $(Z,d_Z)$ and two isometric embeddings $\gamma_X : X \to Z$ and $\gamma_Y : Y \to Z$ such that the Hausdorff distance $d^\text{GH}_k(\gamma_X(X), \gamma_Y(Y))$ is $\epsilon$. Consider now the subspace $\gamma_X(X) \cup \gamma_Y(Y) \subseteq Z$, endowed with the induced metric. Since this subspace is finite, it can be isometrically embedded into $(\mathbb{R}^n, ||\cdot||_\infty)$, where $n = \#X + \#Y$, by Lemma 2.8. Let $\gamma$ be the isometric embedding. We then have $d^\text{GH}_k(\gamma\circ \gamma_X(X), \gamma\circ \gamma_Y(Y)) = d^\text{GH}_k((\gamma\circ \gamma_X(X), \gamma\circ \gamma_Y(Y))) = \epsilon$. Hence, inside $(\mathbb{R}^n, ||\cdot||_\infty)$, the distance function $\delta_X$ to $\gamma\circ \gamma_X$ and the distance function $\delta_Y$ to $\gamma\circ \gamma_Y$ are $\epsilon$-close in the max norm. Moreover, since $\delta_X$ and $\delta_Y$ are lower envelopes of finitely many piecewise-linear functions, they are themselves piecewise-linear and therefore tame and continuous.

As a consequence, their persistence diagrams are $\epsilon$-close in the bottleneck distance, by Theorem 2.6.

Recall now that for all $\alpha \in \mathbb{R}$, the open $\alpha$-sublevel-set of $\delta_X$ is the $\alpha$-offset of $\gamma\circ \gamma_X$, i.e. the union of the open $I^\infty$-balls of same radius $\alpha$ about the points of $\gamma\circ \gamma_X$, noted $\gamma\circ \gamma_X^\alpha$. Since the $I^\infty$-balls are hypercubes, they are convex and therefore their intersections are either empty or contractible. As a result, the Persistent Nerve Lemma 2.10 ensures that $\delta_X$ and the Čech filtration $\mathcal{C}(\gamma\circ \gamma_X, (\mathbb{R}^n, ||\cdot||_\infty))$ have identical persistence diagrams. Furthermore, Lemma 2.9 guarantees that $\mathcal{C}(\gamma\circ \gamma_X, (\mathbb{R}^n, I^\infty))$ coincides with the Rips filtration $R(\gamma\circ \gamma_X, (I^\infty))$, which in return is equal to $R(X,d_X)$ since $\gamma\circ \gamma_X$ is an isometric embedding. As a consequence, the persistence diagram of $R(X,d_X)$ coincides with the persistence diagram of $\delta_X$. The same is true for $Y$, therefore the persistence diagrams of $R(X,d_X)$ and $R(Y,d_Y)$ lie at bottleneck distance at most $\epsilon$ of each other. □

Theorem 3.1 extends to finite metric spaces endowed with real valued functions as follows:

**Theorem 3.2** Let $(X,d_X)$ and $(Y,d_Y)$ be two finite metric spaces endowed respectively with $f : X \to \mathbb{R}$ and $g : Y \to \mathbb{R}$. Then, for any $k \in \mathbb{N}$, the bottleneck distance between the persistence diagrams of the filtrations $R(X,d_X,f)$ and $R(Y,d_Y,g)$ is at most $d^\text{GH}_k((X,d_X,f), (Y,d_Y,g))$.

In the limit case where $f = g \equiv 0$, $R(X,d_X,f)$ and $R(Y,d_Y,g)$ become respectively $R(X,d_X)$ and $R(Y,d_Y)$, and we have $d^\text{GH}_0 = d_{\text{GH}}$. Thus, we obtain the statement of Theorem 3.1 as a special case of the above result.

**Proof of Theorem 3.2.** Let $\epsilon = d^\text{GH}_k((X,d_X,f), (Y,d_Y,g))$. We follow the same strategy as in the proof of Theorem 3.1. For all $\alpha \in \mathbb{R}$, we let $X_{\alpha} = f^-\{(\alpha, \infty)\} \subseteq X$ and $Y_{\alpha} = g^-\{(\alpha, \infty)\} \subseteq Y$. As mentioned after definition 2.4, the infimum in Eq. (3) is in fact a minimum, realized by some correspondence $C \in \mathcal{C}(X,Y)$, and the disjoint union $Z = X \cup Y$ can be endowed with a suitable metric $d_Z$ such that the canonical inclusions $\gamma_X : X \hookrightarrow Z$ and $\gamma_Y : Y \hookrightarrow Z$ are isometries onto their images, and such that for every pair $(x,y) \in C$ we have $d_Z(\gamma_X(x), \gamma_Y(y)) \leq \frac{1}{2} ||f(x) - g(y)||_{(\mathbb{R}^\infty)}(\mathbb{R}^\infty) \leq \epsilon$ and $||f(x) - g(y)||_{(\mathbb{R}^\infty)}(\mathbb{R}^\infty) \leq \epsilon$. By Lemma 2.8, we can then embed the finite subspace $(\gamma_X(X) \cup \gamma_Y(Y), d_Z)$ into $(\mathbb{R}^n, I^\infty)$, where $n = \#X + \#Y$, through some isometric embedding $\gamma$. We thus get two isometric embeddings $\gamma\circ \gamma_X$ and $\gamma\circ \gamma_Y$ of $X$ and $Y$ respectively into $(\mathbb{R}^n, I^\infty)$, such that for every pair $(x,y) \in C$ we have $||\gamma\circ \gamma_X(x) - \gamma\circ \gamma_Y(y)||_{(\mathbb{R}^\infty)}(\mathbb{R}^\infty) \leq \epsilon$ and $||\gamma\circ \gamma_X(x) - \gamma\circ \gamma_Y(y)||_{(\mathbb{R}^\infty)}(\mathbb{R}^\infty) \leq \epsilon$. It follows that the offsets filtrations $\{\gamma\circ \gamma_X(X_{\alpha})\}_{\alpha>0}$ and $\{\gamma\circ \gamma_Y(Y_{\alpha})\}_{\alpha>0}$ are $\epsilon$-interleaved, in the following sense: $\forall \alpha > 0$,
\[
\gamma\circ \gamma_X(X_{\alpha}) \leq \gamma\circ \gamma_Y(Y_{(\alpha+\epsilon)}) \leq \gamma\circ \gamma_X(X_{(\alpha+2\epsilon)}).
\]

Indeed, for any point $p \in \gamma\circ \gamma_X(X_{\alpha})$, there is an $x \in X$ such that $||p - \gamma\circ \gamma_X(x)||_{(\mathbb{R}^\infty)}(\mathbb{R}^\infty) \leq \alpha$. Letting $y \in Y$ be such that $(x,y) \in C$, our embedding ensures that $||\gamma\circ \gamma_X(x) - \gamma\circ \gamma_Y(y)||_{(\mathbb{R}^\infty)}(\mathbb{R}^\infty) \leq \epsilon$ and $||\gamma\circ \gamma_X(x) - \gamma\circ \gamma_Y(y)||_{(\mathbb{R}^\infty)}(\mathbb{R}^\infty) \leq \epsilon$. By the triangle inequality we have $||\gamma\circ \gamma_X(x) - \gamma\circ \gamma_Y(y)||_{(\mathbb{R}^\infty)}(\mathbb{R}^\infty) \leq \alpha + \epsilon$. It follows that $p \in \gamma\circ \gamma_Y(Y_{(\alpha+\epsilon)})$. The second inclusion in the above equation follows by symmetry.

Since the two offsets filtrations are $\epsilon$-interleaved, the extended stability Theorem [CCGS*09, Thm. 4.4] guarantees that their persistence diagrams are $\epsilon$-close to each other in the bottleneck distance. By Lemma 2.10, so are the persistence diagrams of the Čech filtrations $\{C_{\alpha}(\gamma\circ \gamma_X(X_{\alpha}), (\mathbb{R}^n, I^\infty))\}_{\alpha>0}$ and $\{C_{\alpha}(\gamma\circ \gamma_Y(Y_{\alpha}), (\mathbb{R}^n, I^\infty))\}_{\alpha>0}$. By Lemma 2.9, so are the persistence diagrams of the Rips filtrations $\{R_{\alpha}(\gamma\circ \gamma_X(X_{\alpha}), (\mathbb{R}^n, I^\infty))\}_{\alpha>0}$ and $\{R_{\alpha}(\gamma\circ \gamma_Y(Y_{\alpha}), (\mathbb{R}^n, I^\infty))\}_{\alpha>0}$. Finally, so are the diagrams of $R(X,d_X,f)$ and $R(Y,d_Y,g)$, since these filtrations coincide with...
suggest that the persistence di-
formation than just
A more general construction
Definition 4.1 Let \( H_L \) be the class of maps \( h : X \rightarrow X_1 \) that preserve the metric and satisfy for some \( L > 0 \)
\[
\|f_x - f_y\|_{\infty} \leq \frac{1}{2} \|\Gamma_{X,Y}\|_{\infty} \quad (5)
\]
for all \((X,d_X),(Y,d_Y) \in X\) and all \( C \in \mathcal{C}(X,Y) \), where \( h(X,d_X) = (X,d_X,f_x) \) and \( h(Y,d_Y) = (Y,d_Y,f_y) \).
From Definitions 2.4 and 4.1 and Theorem 3.2 we obtain:
Corollary 4.2 Let \( X, Y \in X \) be finite. Then, for any \( h \in \mathcal{H}_L \),
\[
d_{GH}(h(x),h(y)) \leq \frac{1}{2} \|\Gamma_{X,Y}\|_{\infty} \quad (5)
\]
where \( h(X,d_X) = (X,d_X,f_x) \) and \( h(Y,d_Y) = (Y,d_Y,f_y) \).
When the context is clear, we will abuse notations and omit some of the arguments in the expression \( \mathcal{R}(X,d_X,f_X) \).
Below we provide examples of maps that are in \( \mathcal{H}_L \):
The diameter map. Our easiest example is the map \( h_{diam} : (X,d_X) \rightarrow (X,d_X,f_X) \) where \( f_X : X \rightarrow \mathbb{R} \) is the constant function \( f_X \equiv \text{diam}(X) \). It is easily seen that \( h_{diam} \in \mathcal{H}_2 \).
The eccentricity map. The map \( h_{\varepsilon} : (X,d_X) \rightarrow (X,d_X,e_X^1) \) where \( e_X^1 : X \rightarrow \mathbb{R} \) is given by \( e_X^1(x) = \max_{y \in X} d_X(x, y) \) is in \( \mathcal{H}_2 \). Indeed, assume \( X, Y \in \mathcal{X} \) and \( C \in \mathcal{C}(X,Y) \), and let \( \eta = \|\Gamma_{X,Y}\|_{\infty} \). Pick \((x,y),(x',y') \in C \) and notice that
\[
d_X(x,y) \leq d_Y(y,y') + \eta \leq \max_{y' \in X} d_Y(y,y') + \eta.
\]
Hence, \( e_X^1(x) \leq e_Y^1(y) + \eta \) for all \((x,y) \in C \). By symmetry, \( |e_X^1(x) - e_Y^1(y)| \leq \eta \) for all \((x,y) \in C \).
Higher-order eccentricities. A more general construction is as follows: given \( m \in \mathbb{N} \), let \( h_{e_X^m} : X \rightarrow X_1 \) be the map \( (X,d_X) \rightarrow (X,d_X,e_X^m) \), where \( e_X^m : X \rightarrow \mathbb{R} \) is defined by
\[
\forall x_0 \in X, e_X^m(x_0) = \max_{0 \leq j \leq m} d_X(x_0,x_j),
\]
where \( x_0, \ldots, x_m \) range over \( X \). It turns out that \( h_{e_X^m} \) is in \( \mathcal{H}_2 \).
In addition, observe that for \( m > 1 \), \( e_X^m \) provides more information than just \( e_X^1 \); consider for instance \( S^2 \) endowed with the usual intrinsic metric. Then, \( e_X^1 \equiv \pi \) for all \( m \in \mathbb{N} \), whereas \( e_X^2 \equiv \pi/4 \) is different from \( e_X^2 \equiv \arcsin(\sqrt{2/3}) > \pi/4 \). Note however that the complexity of computing \( e_X^m \) on a finite metric space with \( N \) points is roughly \( O(N^{m+1}) \).
An alternative to \( e_X^m \). Instead of the eccentricities, one may consider using the following inductive family of functions: \( f_0^X \equiv 0 \), and \( f_{m+1}^X(x) = \max_{x' \in X} (d_X(x,x') + f_m^X(x')) \). It can be shown that for each \( m \in \mathbb{N} \) the map \( h_m : (X,d_X) \rightarrow (X,d_X,f_m^X) \) is in \( \mathcal{H}_m \). The complexity associated with computing \( h_m \) is \( O(m \cdot N^2) \), where \( N \) is the cardinality of the metric space.
Remark 1 The above examples give rise to a large variety of maps in \( \mathcal{H}_L \). Indeed, given \( h : (X,d_X) \rightarrow (X,d_X,f_X) \) and \( h' : (X,d_X) \rightarrow (X,d_X,f_X) \) in \( \mathcal{H}_L \), observe that \( \max(h,h') \) and \( \sup(h,h') \) are both in \( \mathcal{H}_L \). Moreover, \( h + h' \in \mathcal{H}_L \), and for any \( \lambda \in \mathbb{R} \), \( \lambda h \in \mathcal{H}_L \). It is important to note that the persistence diagrams of \( \mathcal{R}(f_X) \) and \( \mathcal{R}(\lambda f_X) \) are not related by a simple transformation: different choices of \( \lambda \) give different signatures.
5. Introducing measures
For the sake of generality, it is important to make the class of admissible functions as large as possible. Unfortunately, it seems that certain canonical functions such as the average distance to a point are not directly controllable by the GH distance. This is intuitively clear since in averaging the values \( \sum_{x \in X} d_X(x,\alpha(x)) \) there is a choice to be made for the weights \( \{\alpha(x)\}_{x \in X} \), the choice \( \alpha(x) = \frac{1}{|X|} \) being one of many possible. In order to incorporate this extra structure (weights) into our formulas, we define a new metric on the class of spaces that arise in \( \mathcal{M}_0 \).
A measure metric space (mm space, for short) is a triple \( (X,d_X,\mu_X) \) where \( X, d_X \in \mathcal{X} \) and \( \mu_X \) is a Borel probability measure such that \( \text{supp}(\mu_X) = X \). Here, \text{supp}(\mu_X) denotes the support of \( X \), i.e., the minimal closed set \( Z \) such that \( \mu(X \setminus Z) = 0 \). Let \( \mathcal{X}_m \) denote the collection of all mm spaces, and \( \mathcal{X}_m^\infty \) the collection of all mm spaces endowed with continuous real-valued functions. Two mm spaces \( (X,d_X,\mu_X) \) and \( (Y,d_Y,\mu_Y) \) are said to be isomorphic if there exists an isometry \( \phi : X \rightarrow Y \) s.t. \( f_X = f_Y \circ \phi \) and \( \mu_X(\phi^{-1}(Z)) = \mu_Y(Z) \) for all measurable sets \( Z \subseteq Y \). It turns out that we can metrize the set of isomorphism classes of \( \mathcal{X}_m^\infty \) by replacing correspondences between \( X \) and \( Y \) in \( \mathcal{X}_m^\infty \) by couplings, that is, probability measures on \( X \times Y \) whose marginals on the first and second factors are \( \mu_X \) and \( \mu_Y \) respectively. Since \( X,Y \) are compact and \( \mu_X, \mu_Y \) have full support, the support of a coupling is a correspondence [Mémo07, Lemma 1].
Given \( X \in \mathcal{X}_m^\infty \) we then define \( d_{GW,\infty}(X,Y) \) to be the infimal \( \eta > 0 \) such that there exists a coupling \( \mu \) for which both \( \frac{1}{2} \|\Gamma_{X,Y}\|_{\infty} = \mathcal{C}(\mu) \leq \eta \) and \( \|f_X - f_Y\|_{\infty} \leq \eta \), where \( \mathcal{C}(\mu) \) denotes the correspondence suppp(\mu).
For any \( X,Y \in \mathcal{X}_m^\infty \), we define the Gromov-Wasserstein distance \( d_{GW,\infty}(X,Y) \) to be equal to \( d_{GW,\infty}(X,Y) \), where we regard \( X,Y \) as elements in \( \mathcal{X}_m^\infty \) by endowing them
with the zero functions. One can prove that \( \text{d}_{G\infty}(X, Y) \leq \text{d}_{GW, \infty}(X, Y) \) for all \( X, Y \in X^m \) [Mém07, Proposition 6].

The approach of Sections 3 and 4 generalizes almost verbatim to this measured setting. In particular, we have the following analogous of Corollary 4.2. Let \( H^p_\infty \) be the class of maps \( h : X^m \to \Lambda^p D^m \) that preserve the metric and the measure and satisfy, for some \( L > 0 \),

\[
\| f_x - f_y \| \leq (c(\mu)) \leq L \cdot \frac{1}{2} \| \Gamma X, Y \| \times (c(\mu) \times C(\mu)) \quad (6)
\]

for all \( (X, d_x), (Y, d_y) \in \Lambda^m \) and all \( \mu \in \mathcal{M}(\mu_x, \mu_Y) \).

Here, \( h(X, d_x, \mu_x) = (X, d_x, \mu_x, f_x) \), \( h(Y, d_y, \mu_y) = (Y, d_y, \mu_y, f_y) \), and \( \mathcal{M}(\mu_x, \mu_y) \) denotes the set of all couplings between \( (X, \mu_x) \) and \( (Y, \mu_Y) \).

**Corollary 5.1** Let \( X, Y \in \Lambda^m \) be finite. Then for any \( h \in H^p_\infty \),

\[
\text{d}_{\infty}^H(D_\infty \mathcal{R}(h(X)), D_\infty \mathcal{R}(h(Y))) \leq \text{d}_{GW, \infty}(X, Y).
\]

The class \( H^p_\infty \) is actually larger than \( H_L \). For instance, given \( (X, d_x, \mu_x) \in \Lambda^m \) and \( p \geq 1 \) we define the \( p \)-eccentricity function as

\[
s_{X, p}(x) := \left( \int_X d_X(x,x')^p \mu_X(dx') \right)^{1/p},
\]

and for \( p = \infty \), \( s_{X, \infty}(x) := \max_{x' \in X} d_X(x, x') \).

**Lemma 5.2** The \( p \)-eccentricity map \( h_{s_p} : \Lambda^m \to \Lambda^p \) defined by \( (X, d_x, \mu_x) \mapsto (X, d_x, \mu_x, s_{X, p}) \) is in \( H^p_\infty \).

**Proof.** Let \( X, Y \in \Lambda^m \) and \( \mu \in \mathcal{M}(\mu_x, \mu_Y) \). Then, for all \( x, y \in X \) and \( y \in Y \), the triangle inequality and the \( \mathcal{P}(\mu) \)-norm implies:

\[
\| d_X(x, y) \|_{\mathcal{P}(\mu)} - \| d_Y(y, y') \|_{\mathcal{P}(\mu)} \leq \| \Gamma X, Y \|_{(c(\mu), c(\mu))}.
\]

Since \( \mu \in \mathcal{M}(\mu_x, \mu_Y) \), it follows easily that \( \| d_X(x, y) \|_{\mathcal{P}(\mu)} = s_{x, p}(x) \) and \( \| d_Y(y, y') \|_{\mathcal{P}(\mu)} = s_{y, p}(y) \). Hence,

\[
| s_{x, p}(x) - s_{y, p}(y) | \leq \| \Gamma X, Y \|_{(c(\mu), c(\mu))} \leq \| \Gamma X, Y \|_{(c(\mu), c(\mu))}.
\]

In particular, for all \( (x, y) \in C(\mu) \),

\[
| s_{x, p}(x) - s_{y, p}(y) | \leq \| \Gamma X, Y \|_{(c(\mu), c(\mu))},
\]

hence

\[
\| s_{x, p} - s_{y, p} \|_{(c(\mu), c(\mu))} \leq \| \Gamma X, Y \|_{(c(\mu), c(\mu))},
\]

which means that \( h_{s_p} \) is in \( H^p_\infty \) (cf. Eq. (6)). \( \square \)

### 6. Algorithmic aspects

In implementing the lower bounds given by Corollaries 4.2 and 5.1, one must take into account the facts that (1) the computation of the full persistence diagrams may be too expensive and (2) the bottleneck matching of the diagrams may be time consuming. This section addresses these two issues.

---

**6.1. Thresholding filtrations**

To deal with problem (1) above, we restrict the computation of our filtrations as follows: given a filtration \( \emptyset = k_0 \subseteq \cdots \subseteq k_m = K \) and a threshold \( t \in \mathbb{R} \), we let \( m \) be such that \( \alpha_{m-1} < t \leq \alpha_m \) and we consider only the \( t \)-thresholded filtration \( \emptyset = k_0 \subseteq \cdots \subseteq k_{m-1} \subseteq K \). The reason why we replace \( \emptyset \) by \( K \) is to preserve bottleneck distances, as will be shown below. The drawback is that in principle we should still have to compute the full complex \( K \). Nevertheless, we will see that this is not necessary in practice. The thresholding operation affects persistence diagrams in the following way (see also Figure 3):

**Lemma 6.1** Given a filtration \( K \) and its \( t \)-thresholded variant \( K_t \), there is a multi-bijection \( \gamma : D_t K \to D_t K_t \) such that:

- the restriction of \( \gamma \) to the lower-left quadrant \( (-\infty, t] \times (-\infty, t] \) is the identity;
- the restriction of \( \gamma \) to the upper-left quadrant \( (-\infty, t] \times (t, +\infty) \) is the vertical projection onto the line \( y = t \);
- the restriction of \( \gamma \) to the line \( y = +\infty \) is the horizontal projection onto the extended half-plane \( (-\infty, t] \times \mathbb{R} \);
- finally, the restriction of \( \gamma \) to the half-plane \( (t, +\infty) \times \mathbb{R} \) is the projection onto the diagonal point \( (t, t) \).

The proof of this rather intuitive result is omitted. Lemma 6.1 implies that for any filtrations \( F, G \) and any threshold \( t \):

\[
\text{d}_{\infty}^H(D_{\infty} F_t, D_{\infty} G_t) \leq \text{d}_{\infty}^H(D_{\infty} F, D_{\infty} G). \quad (7)
\]

This means that the results of Sections 3 through 5 still hold when the filtrations are replaced by their \( t \)-thresholded versions. In addition, Lemma 6.1 provides a way of computing \( D_{\infty} F_t, D_{\infty} G_t \) without building \( R_{\infty}(X, d_x, f_X) \) explicitly. Indeed, we know that \( R_{\infty}(X, d_x, f_X) \) is the full simplex on the vertex set \( X \), therefore the filtration \( R(X, d_x, f_X) \) has only one essential homology class \( [\cdot] \), easily identified as the connected component created by the point of \( X \) with minimum \( f_X \)-value. It follows that \( D_{\infty} F_t, D_{\infty} G_t \) can be obtained first by computing the diagram of the truncated filtration \( \{ R_k(X, d_X, f_X) \}_{0 \leq k \leq t} \), and then by projecting the resulting multi-set (save the point corresponding to \( [\cdot] \)) when \( k = 0 \) vertically onto the lower-left quadrant \( (-\infty, t] \times (-\infty, t] \).

Figure 3: Effect of thresholding on a persistence diagram.
6.2. Simplifying persistence diagrams

To address problem (2) above, we simplify each considered persistence diagram \( D_k^F \) as follows: given a parameter \( \varepsilon \geq 0 \), we snap all points of \( D_k^F \) lying within \( L^\infty \)-distance \( \varepsilon \) of the diagonal \( \Delta \) onto \( \Delta \). The resulting simplified diagram is called \( D_k^F \). The triangle inequality implies that for any persistence diagrams \( D_k^F, D'_k \varrho \varrho \) and any parameters \( \varepsilon, \varepsilon' \geq 0 \),

\[
|d_\infty^\varepsilon (D_k^F, D_k^F') - d_\infty^\varepsilon' (D_k^F, D_k^F')| \leq \max \{\varepsilon, \varepsilon'\}. \tag{8}
\]

In our experiments, we specify a maximal number \( N \) of off-diagonal points to be kept per diagram. Specifically, we keep the points with largest \( L^\infty \)-distance to \( \Delta \). For every diagram \( D_k^F \) considered, we perform this simplification and record the incurred projection error \( \varepsilon \geq 0 \), which remains small if \( N \) is chosen sufficiently large.

6.3. Computing the bottleneck distance

Given two simplified persistence diagrams \( D_k^F \) and \( D'_k \varrho \varrho \), each containing at most \( N \) off-diagonal points, we proceed as follows. Firstly, we discard the diagonal and consider only \( D_k^F \setminus \Delta \) and \( D'_k \setminus \Delta \), whose total multiplicities are finite, bounded from above by \( N \). Secondly, we add arbitrary diagonal points to \( D_k^F \setminus \Delta \) and \( D'_k \setminus \Delta \), so that the resulting multi-sets \( \{ f_i \} \) and \( \{ g_j \} \) contain exactly \( N \) points each. Finally, we solve the following Bottleneck Assignment Problem: compute \( c^* = \min_{\pi} \max \{ \varrho(f_i, \varrho(g_{\pi(i)})) \} \), where \( \pi \) ranges over all permutations of the set \( \{ 1, \ldots, N \} \), and where

\[
\varrho(p, q) = \min \left\{ \| p - q \|_\infty, \frac{1}{2} \max \{ \| p_1 - q_1 \|, \| q_1 - q_2 \| \} \right\}.
\]

In plain words, \( \varrho(p, q) \) measures the cost of matching \( p \) with \( q \) against the cost of matching both points with the diagonal \( \Delta \). It can then be easily checked that \( c^* = d_\infty^\infty (D_k^F, D'_k) \). In addition, we have that \( \varrho(p, q) = \varrho(q, p) \) whenever \( q, q' \in \Delta \), which makes the choice of the locations of the diagonal points inserted during the second step of our procedure unimportant. In practice, we compute \( c^* \) using the thresholding algorithm of [BC99, Section 5], whose running time is \( O(N^2 \log N) \).

7. Application to shape classification

We exemplify the use of our framework on a shape classification problem under invariances. We used the publicly available database of (triangulated) shapes [SP04]. This database comprises 62 shapes from six different classes: camel, cat, elephant, face, head and horse. Each class contains several different poses of the same shape. These poses are richer than just rigid isometries, as can be seen from Figure 1. The number of vertices in the models range from 7K to 30K. We equip each model \( X_i \) with an intrinsic distance \( d_i \), between pairs of points in \( X_i \) using Dijkstra’s algorithm on the 1-skeleton graph \( G(X_i) \) of the mesh.\(^1\) We then select a uniform subset \( X'_i \) of 4K vertices using the Euclidean farthest point sampling procedure. Briefly, we first randomly choose a point from the vertex set. Then, we choose the second point as the one at maximal distance from the first one. Subsequent points are chosen always to maximize the distance to the points already chosen. Let \( X'_i \) denote this reduced model with 4K vertices. We further subsample \( X'_i \) using the farthest point procedure, this time in the distance \( d_i \) computed using \( G(X_i) \), and retain only 300 points.

We denote the resulting coarse set by \( X''_i \), which we endow with the distance \( d_i \), properly normalized so that the diameter of \( X''_i \) is 1. We also equip \( X''_i \) with a probability measure \( \mu_i \) based on intrinsic Voronoi partitions, where the measure at point \( x \in X''_i \) equals the proportion of points of \( X''_i \) that are closer to \( x \) than to any other point of \( X''_i \). From each model \( X_i \) we thus obtain a discrete mm-space \( \{ X''_i, d_i, \mu_i \} \). Let \( S \) denote the collection of all 62 such mm-spaces.

Let \( P := \{ 1, 2, 3, \infty \} \), \( H^+ = \{ h_0, h_\infty, p \in P \} \subset H''_i \) and \( H' = \{ \sup(h_0) - h_\infty, p \in P \} \subset H''_i \) (recall Remark 1). Let \( H \) denote the union of these two sets of functions, and let

\[
\Lambda := \{ 0, 0.01, 0.1, 0.2, \ldots, 0.9, 1, 2, 3, 4, 5, 10, 30, 50, 70, 90 \}.
\]

For each pair of mm-spaces \( X_i \) and \( X_j \) in \( S \), and a choice of \( \lambda \in \Lambda \) and a function \( h \in H \) we estimate the lower bound given by Corollary 5.1 as follows:

1. We first construct the thresholded filtrations \( \mathcal{R} (\lambda, h(X)) \) and \( \mathcal{R} (\lambda, h(Y)) \) up to their 3-dimensional skeleta, as discussed in Section 6.1. The thresholding parameter \( t \) is chosen so as to guarantee that the 1-skeleta of the underlying complexes of \( \mathcal{R} (\lambda, h(X)) \) and \( \mathcal{R} (\lambda, h(Y)) \) contain no more than a fraction \( s \) of the (quadratic) number of edges of the complete graph. The value of \( s \) chosen in our experiments is 7\%, which allows a reasonable execution time of approximately 1.5 seconds per pair of mm-spaces, on average.

2. We use the software jplex [JP] and the procedure of Section 6.1 to compute the \( k \)th persistence diagrams of each thresholded filtration, for \( k = 0, 1, 2 \).

3. We apply the simplification step described in Section 6.2 with \( N = 30 \). For each \( k = 0, 1, 2 \), let \( E_k(X) = D_k^X (\mathcal{R} (\lambda, h(X))) \) and \( E_k(Y) = D_k^Y (\mathcal{R} (\lambda, h(Y))) \) be the simplified diagrams, where \( e_k(X) \) and \( e_k(Y) \) are the projection errors.

4. We use the procedure of Section 6.3 to compute the quantity \( c(h, \lambda, X, Y) \) as

\[
\max_k \max \left\{ d_\infty^\varepsilon (E_k(X), E_k(Y)) - \max \{ e_k(X), e_k(Y) \}, 0 \right\} / \max (1, \lambda, \lambda(h))
\]

\(^1\) In this particular application we take advantage of the fact that a mesh is available for each of the shapes. In full generality, one can replace \( G(X_i) \) by some neighborhood graph in the ambient Euclidean metric, with similar guarantees.
where $L(h)$ is 2 if $h \in \mathcal{H}^+$ and 4 if $h \in \mathcal{H}^-$. By Corollary 5.1, Lemma 6.1 and Eq. (8), we know that $d_{GW,\infty}(X,Y) \geq c(h,\lambda,X,Y)$.

For any pair $X,Y \in S$, we can now bound $d_{GW,\infty}(X,Y)$ from below by $c(X,Y) := \max_{h \in \mathcal{H}} \lambda \in \mathcal{A} c(h,\lambda,X,Y)$. Let $M$ denote the matrix with elements $c(X,Y)$, $X,Y \in S$. Figure 4 (left) shows the result of these computations on our database, while Figure 5 shows the result of applying the metric multi-dimensional scaling procedure implemented by the Matlab command mdscale to $M$.

**Figure 4:** Left: estimate of the Gromov-Wasserstein distance computed on the database $S$. Right: estimated confusion matrix for the 1-nearest neighbor classification problem described in the text. The overall error rate is 4%.

In order to evaluate the discriminative power contained in the matrix $M$, we consider a classification task as follows: We randomly select one shape from each class, form a training set $T$ and use it for performing 1-nearest neighbor classification (where nearest is with respect to the metric defined by $M$) of the remaining shapes. By simple comparison between the class predicted by the classifier and the actual class to which the shape belongs we obtain an estimate of the probability $P_j(M)$ of mis-classification. We repeat this procedure for 2K random choices of the training set. Using the same randomized procedure we obtain an estimate of the confusion matrix for this problem, whose entry $(i,j)$ is the probability that the classifier will assign class $j$ to a shape when the actual class is $i$.— see Figure 4 (right). We obtained $P_j(M) = 4\%$. As Figure 5 shows, there is a shape of class camel that lies very close to the cluster formed by the class horse. Removal of this shape from the database reduced the probability of error to 2\%.

**Figure 5:** MDS plot of the matrix $M$ with labels corresponding to each class. The overall error is estimated to be 4\%. Notice how there is excellent clustering of the different classes, save for a single shape of the class camel that lies very close to the cluster formed by the class horse. Removal of this shape reduces the classification error to 2\%.

8. Perspectives

In this paper we only used Euclidean and geodesic distances to illustrate our approach, however many other metrics may be considered, such as the diffusion distance [BBK*].

The generality of our approach makes it applicable in a large variety of contexts beyond 3d shape classification. Our signatures are indeed well-defined, stable and computable for any arbitrary finite metric space that is given in the form of a distance matrix or equivalent representation. This makes our approach well-suited for classification problems in general, even in cases where the data are high-dimensional or lying in some non-Euclidean space without any information on the embedding beside the inter-point distances.

At a more theoretical level, let us point out that Theorem 3.1 enables us to define limit Rips persistence diagrams for compact metric spaces. Indeed, given a compact metric space $(Z,d_Z)$, consider a sequence of finite $\varepsilon$-samples of $(Z,d_Z)$ such that $\varepsilon$ converges to zero. The $k$-th Rips persistence diagram of $(Z,d_Z)$ can then be defined as the limit of the $k$-th persistence diagrams of the Rips filtrations of the sequence. This limit is independent of the choice of the sequence of $\varepsilon$-samples, since any two finite $\varepsilon$-samples of $(Z,d_Z)$ lie at Gromov-Hausdorff distance $2\varepsilon$ of each other, which by Theorem 3.1 implies that the persistence diagrams of their Rips filtrations are $2\varepsilon$-close in the bottleneck distance. Thus, the limit Rips persistence diagram of $(Z,d_Z)$ is well-defined, and by Theorem 3.1 it is stable under small perturbations of the space in the Gromov-Hausdorff distance. Similarly, for any real-valued function $f : X \to \mathbb{R}$, Theorem 3.2 enables to define limit Rips persistence diagrams $(X,d_X,f)$ and to guarantee their stability. This concept of limit persistence diagram of a compact metric space $(X,d_X)$ is reminiscent of the approach to topological persistence developed in [CCSG*09]. However, it may not be equivalent to the persistence diagram of the limit filtration $\mathcal{R}(X,d_X)$ or $\mathcal{R}(X,d_X,f)$ in general. Finding the exact relationships that exist between these diagrams is still open.

Figure 6: Some toy examples, from left to right: the unit circle, a helical curve of same length $2\pi$ drawn on a torus, the unit sphere, an ellipsoid whose smallest equatorial ellipse has same length $2\pi$ as the equator of the sphere. On each shape, a uniform 0.0125-sample has been generated, on top of which various Rips filtrations have been constructed using different metrics and functions: geodesic distance and no function (second row), Euclidean distance and no function (third row), Euclidean distance and 0.2 times the eccentricity (fourth row). The corresponding persistence diagrams are presented in rows 2 through 4: each picture shows the 0-dimensional (blue), 1-dimensional (red), and 2-dimensional (green) diagrams super-imposed.
